

Phase 2 Insight Report

Team: Kislay Jha, Vedansh Shah

1. The Virality Disconnect (E4 Findings): The platform exhibits distinct instances of "hollow virality," where content is shared extensively (>1500 shares) but fails to generate proportional endorsements (<500 likes). This indicates a potential vulnerability to clickbait algorithms or outrage-driven sharing loops.

2. The Follower Count Fallacy (M2 Findings): By mathematically dividing the user base into distinct cohorts (above and below 25,000 followers), the data reveals a near-identical average engagement per post across both groups. This insight definitively proves that static follower accumulation does not guarantee reach; the platform's distribution engine prioritizes intrinsic content quality over audience size.

3. Detection of Artificial Amplification (H6 Findings): A critical security vulnerability was identified through the isolation of "Suspicious High Impact Users." We detected accounts maintaining micro-influencer statuses (<10,000 followers) that consistently outperform the global platform average. More alarmingly, these accounts trigger a specific manipulation footprint: their posts frequently accumulate more shares than likes. This inverse engagement ratio strongly suggests the presence of automated bot networks or organized sharing syndicates artificially inflating metrics on the Social Engine.
